AI Interview Coach

Project Report

Name :	ANMOL MISHRA
Reg. NO :	25BAI11379
Corse Code :	CSA2001
Faculty :	Dr. Satyabrata Nath
Date :	31/03/2026

1. Introduction

The AI Interview Simulator is a Python-based command-line application designed to help students and job seekers practice and improve their interview skills. In today's competitive job market, interview preparation is a critical yet often neglected aspect of career development. Many candidates lack access to quality mock-interview resources, personalized feedback, or mentors who can evaluate their responses objectively.

This project addresses that gap by providing an automated, intelligent interview simulation system. The system presents a set of carefully chosen interview questions, evaluates candidate answers based on multiple parameters - length, relevance, keyword usage, and technical vocabulary - and generates a detailed performance report with scores, mistakes identified, and actionable suggestions for improvement.

The project was built entirely in Python, leveraging standard libraries along with Matplotlib for data visualization. It is modular in design, making it easy to extend with new questions, evaluation criteria, or output formats in the future.

1.1 Why this Idea only?

The idea came from a common real-world challenge - students preparing for campus placements often have no way to get feedback on their spoken or written interview answers. Human mentors are expensive and not always available. AI-powered tools can fill this role by providing consistent, scalable, and immediate feedback at no cost.

Building this tool also served as a hands-on exercise in applying Python programming concepts including modular design, file Input/output , data structures, basic NLP-style keyword matching, and data visualization - skills that are directly relevant to the computer science curriculum.

1.2 Scope of the Project

The AI Interview Simulator covers the following scope:

- Simulates a complete interview session with 14 questions covering both HR and technical categories.
- Evaluates each answer on a 10-point scale using rule-based scoring logic.
- Provides per-question feedback, highlighting mistakes and offering improvement suggestions
- Generates a persistent text-based report saved to disk.
- Visualizes performance across all questions using a line graph
- Calculates an overall score and classifies performance into three tiers

2. Problem Statement

Despite the widespread acknowledgment that interview skills are crucial for career success, there is a significant lack of accessible, automated tools that can provide personalized and immediate feedback to candidates.

The specific problems this project targets are:

1. Lack of practice platforms - Most students have no structured way to practice interview questions and receive feedback outside of actual interviews or expensive coaching.
2. No objective evaluation - Human evaluators are subject to bias and inconsistency.
   A rule-based automated system provides uniform evaluation criteria for all candidates.
3. Delayed feedback - After real interviews, candidates rarely receive detailed feedback on why they were rejected or what they should improve.
4. No self-awareness of weaknesses - Candidates are often unaware of common mistakes such as short answers, missing technical keywords, or lack of structured responses.
5. Scalability - Human-led mock interviews cannot scale to serve thousands of students simultaneously - an automated system can.

This project proposes a solution to these problems by building a lightweight, local, Python-based interview simulator that evaluates answers, identifies weaknesses, and provides structured guidance.

3. Approach to Solving the Problem

The solution was designed around three core principles - simplicity, modularity, and feedback. The project was broken down into distinct functional modules, each responsible for a specific part of the overall system.

3.1 System Architecture

The project follows a structured way -

Module	Responsibility
questions.py	Stores all interview questions and their associated keywords
evaluator.py	Scores each answer on a 10-point scale using multi-criteria logic
report.py	Saves detailed per-question analysis and overall feedback to a (.txt) file
utils.py	Calculates final result tier and renders the performance graph (Matplotlib)
main.py	Operates the entire interview session - input then evaluation then output.

3.2 Evaluation Methodology

The evaluation engine in evaluator.py uses a rule-based scoring approach with three independent criteria -

Criterion 1 - Answer Length (Max 4 points)

- More than 20 words : Full 4 points - indicates a detailed response
- Between 10-20 words : 2 points - partial credit with feedback to elaborate
- 10 words or fewer : 0 points - flagged as too short

Criterion 2 - Keyword Relevance (2 points per keyword)

Each question in questions.py has an associated list of expected keywords. For example, the question "What is OOP?" expects keywords like class, object, inheritance.

The evaluator counts how many of these keywords appear in the candidate's answer and awards 2 points each.

Criterion 3 - Technical Vocabulary (+1 point)

A shared list of general technical terms (project, algorithm, data, system, code) is checked across all answers. If any of these appear, a bonus point is awarded, promoting candidates to use professional language.

The maximum possible score per question is capped at 10. The final performance tier is calculated as:

```
Score >= 8   → Excellent Performance
Score >= 5   → Average Performance
Score < 5    → Needs Improvement
```

3.3 Question Design

The question set of 14 questions was split across two categories :

- HR / Behavioural Questions (4) -
  i) Tell me about yourself,
  ii) What are your strengths?
  iii) Why should we hire you?
  iv) Where do you see yourself in 5 years?
  v) And more

- Technical Questions (10) -
  i) Favourite project
  ii) Programming languages
  iii) OOP concepts
  iv) Debugging
  v) AI/ML understanding
  vi) and more

This balanced split mirrors the structure of real campus recruitment interviews.

4. Key Decisions Made

Several important design and implementation decisions were made during the development of this project -

4.1 Rule-Based vs. ML-Based Evaluation

The decision was made to use a rule-based scoring system rather than a machine learning model. While an ML model could potentially evaluate semantic quality, it would require a large training dataset, significant computational resources, and internet connectivity - none of which are suitable for a lightweight local tool. The rule-based approach is transparent, fast, deterministic, and works entirely offline.

4.2 Modular File Structure

Instead of writing everything in one file, the project was deliberately split into five distinct modules. This modular structure keeps each file focused on a single responsibility, makes the code easier to read and debug, and allows individual components (e.g., questions or scoring logic) to be updated without touching other parts of the system.

4.3 Persistent Report Saving

Rather than printing results only to the console, the system appends a full report to a report.txt file using Python's file Input/Output.

The use of append mode ("a") means multiple interview sessions are preserved in one file, creating a history of performance over time.

4.4 Visual Performance Graph

Matplotlib was used to generate a line chart showing score progression across questions. This visual component gives candidates an immediate, at-a-glance view of which questions they answered well and which need more work – more suitable than reading a table of numbers.

4.5 Score Capping

The total score from all three criteria can theoretically exceed 10, especially for very long answers with many keywords. A hard cap of 10 was implemented to keep scores fair and normalized across all questions, regardless of question type.

5. Challenges Faced

Building this project involved navigating several technical and design challenges:

5.1 Designing Fair Keyword Lists

One of the most time-consuming tasks was designing keyword lists that are neither too strict (causing false negatives for good answers) nor too lenient (giving undeserved points).

For example, for the OOP question, a candidate who explains encapsulation clearly without using the word "class" might score lower than expected. Balancing this required multiple revisions.

5.2 Avoiding Over-Engineering

There was a temptation to use NLP libraries like NLTK or spaCy for better semantic understanding. However, adding such dependencies would complicate installation and reduce portability. The decision to use only Python's built-in string methods and standard libraries kept the project simple and self-contained.

5.3 Report File Formatting

Formatting the output in report.txt in a way that is both readable and consistent required careful handling of string concatenation and line breaks in Python. Since Python's file.write() does not automatically add newlines, every section separator and spacing had to be explicitly managed.

5.4 Graph Rendering in Non-GUI Environments

The plt.show() call in utils.py can fail in environments without a graphical display (e.g., SSH sessions or Docker containers). This is a known limitation. A future improvement would be to suppress plt.show() and only save the graph via plt.savefig(), making the tool more portable.

5.5 Handling Edge Cases in Answers

Candidates who type single-word answers, answer in a language other than English, or leave the answer blank are not handled gracefully. Basic input validation was not added in this version, which is an area for future improvement.

6. What I Learned

This project was a rich learning experience across multiple dimensions:

6.1 Technical Skills

- Modular Python programming - Learned to split a system into logical modules with clear responsibilities, improving code organization and reusability.
- File Input/Output - Gained hands-on experience with reading and writing text files in Python, including append mode for persistent storage.
- Data visualization - Used Matplotlib to generate and save line charts programmatically, understanding figure setup, axis labelling, and saving to PNG.
- String processing - Practiced lowercase conversion, word counting, and substring search for basic NLP-style text evaluation.
- Rule-based systems - Understood how to encode domain knowledge (what makes a good interview answer) into programmatic scoring rules.

6.2 Problem-Solving & Design

- Breaking a real-world problem into sub-problems and mapping each to a module.
- Making deliberate trade-offs between simplicity and sophistication (rule-based vs. ML).
- Thinking from the user's perspective to design feedback that is actionable, not just a score.

6.3 Software Development Process

- Importance of testing with varied inputs (short answers, very long answers, answers missing keywords).
- Using version control (Git) to track the development process as a real project, not a one-time upload.
- Writing documentation and comments to make code understandable to others.

7. Project Structure & File Overview

```
ai-interview-simulator/
├── main.py          # Entry point; runs the full interview session
├── questions.py     # Question bank and keyword dictionaries
├── evaluator.py     # Scoring logic (length, keywords, tech terms)
├── report.py        # Report generation and file writing
├── utils.py         # Result calculation + Matplotlib graph
├── report.txt       # Auto-generated output (appended each session)
├── graph.png        # Auto-generated performance visualization
└── README.md        # Setup and usage instructions
```

Each module has a single, well-defined responsibility. The entry point (main.py) wires them together by importing and calling their public functions.

8. Sample Output

8.1 Console Output

```
Enter your name: Anmol Mishra

--- Interview Started ---

Question: Tell me about yourself
Your Answer: I'm Anmol Mishra, a B.Tech Computer Science student from Bhopal with expertise in Python and AI-ML projects, strong academ
ics, and passions for anime and gaming. What else would you like to know?
---------------------------
Question: What are your strengths?
Your Answer: My strengths: sharp problem-solving in Python/AI, quick learning, solid teamwork, and meticulous attention to detail.
---------------------------
Question: Why should we hire you?
Your Answer: Hire me for my Python/AI expertise, project success, and enthusiastic teamwork ready to drive your goals.
---------------------------
Question: Where do you see yourself in 5 years?
Your Answer: In 5 years, I see myself as a senior AI/ML engineer at a innovative tech firm, leading impactful projects and mentoring ju
niors while advancing my expertise.
---------------------------
Question: Explain your favorite project
Your Answer: My favorite subject is Artificial Intelligence and Machine Learning because it combines creativity with logic—building mod
els that predict and solve real-world problems, like image recognition projects I've done in Python, excites me endlessly.
---------------------------
Question: What programming languages do you know?
Your Answer: I know Python (advanced, my strongest), C++, Java (intermediate), and basics of JavaScript and SQL.
```

```
✅ Interview Completed!
📄 Report saved in report.txt
📊 Graph saved as graph.png
⭐ Final Score: 7.43
📈 Result: Average Performance
```

8.2 Report File Sample (report.txt)

```
report.txt

==========================
AI INTERVIEW REPORT
==========================
Name: Anmol Mishra

DETAILED ANALYSIS

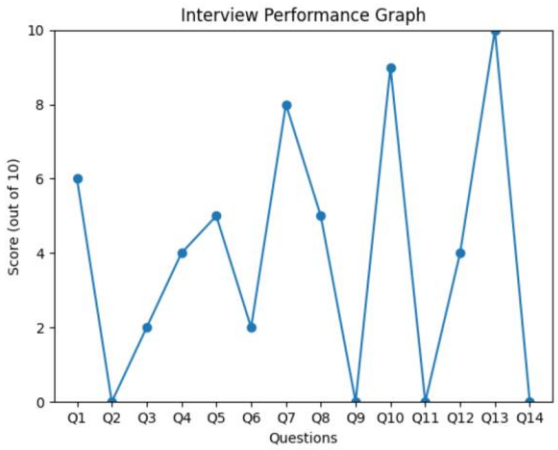
Question: Tell me about yourself
Your Answer: I'm Anmol Mishra, a B.Tech Computer Science student from Bhopal with expertise in Python and AI-ML projects, strong academics,
and passions for anime and gaming. What else would you like to know?
Score: 7/10

---------------------------
Question: What are your strengths?
Your Answer: My strengths: sharp problem-solving in Python/AI, quick learning, solid teamwork, and meticulous attention to detail.
Score: 6/10
Mistakes:
- Answer not detailed enough
- Lack of technical terms
How to Improve:
- Try to explain your answer with more details
- Try explaining your answer step-by-step with examples
- Include technical words like project, system, etc.

---------------------------
Question: Why should we hire you?
Your Answer: Hire me for my Python/AI expertise, project success, and enthusiastic teamwork ready to drive your goals.
Score: 3/10
Mistakes:
- Answer not detailed enough
- No relevant keywords used
How to Improve:
- Try to explain your answer with more details
- Try explaining your answer step-by-step with examples
- Use domain-related keywords
- Include technical terms related to the topic

---------------------------
```

8.3 Graph (graph.png)



9. How to Run the Project

9.1 Method

- Python 3.x installed
- Matplotlib library installed - pip install matplotlib

9.2 Steps

6. Clone the repository from GitHub
7. Navigate to the project directory
8. Run the main script: python main.py
9. Answer each question when prompted
10. View the generated report.txt and graph.png in the project folder

10. Future Improvements

While the current version achieves its core objectives, several enhancements could be made in future iterations:

- NLP Integration - Use libraries like NLTK or spaCy for semantic similarity scoring, allowing partial credit for synonym usage.
- GUI Application - Build a graphical interface using Tkinter or a web-based frontend using Flask/Streamlit to improve user experience.
- Speech-to-Text: Integrate microphone input so candidates can answer verbally, simulating a real interview more accurately.
- Domain-Specific Question Banks: Add separate question sets for different roles (Data Science, Web Development, etc.).
- Email Report: Automatically email the report to the candidate after the session.
- Database Storage: Replace file-based storage with SQLite for better organization and querying of historical sessions.
- Input Validation: Handle blank answers, non-English input, and keyboard interrupts gracefully.

11. Conclusion

The AI Interview Simulator is a practical, self-contained Python application that addresses the real-world challenge of interview preparation through automated evaluation and feedback. By combining rule-based scoring, structured reporting, and visual performance tracking, the system provides a meaningful tool that students and job seekers can use to identify their weaknesses and improve their interview skills over time.

The project demonstrated the power of modular software design - each of the five Python files serves a distinct purpose, making the system maintainable, readable, and extensible. It also reinforced the value of choosing the right level of complexity for a given problem - a rule-based approach, while simpler than machine learning, is entirely appropriate here given the constraints of a local, lightweight application.

Building this project provided hands-on experience with core programming concepts including file Input/Output , string processing, data visualization, and functional decomposition. Perhaps more importantly, it required thinking like a product designer - understanding what kind of feedback is genuinely useful to a user preparing for a high-stakes interview.

The project is a solid foundation for future work. With planned enhancements such as NLP-based semantic scoring, a graphical interface, and speech input, the AI Interview Simulator could evolve into a comprehensive career preparation platform. For now, it stands as a demonstration of how even a straightforward Python script - thoughtfully designed and well-structured - can deliver real, tangible value.
